LESSON 3: CONTROLLING BLEEDING

INTRODUCTION

In an accident situation, you may encounter injured persons bleeding from wounds such as scrapes, cuts, punctures, or tears or gashes in the skin. The deeper a wound goes, the more serious it is. Mild wounds to the outer layer of skin do not bleed heavily but still require cleaning to avoid infection. Deeper wounds in which arteries and veins are cut can be life-threatening. These kinds of wounds may involve great amounts of blood, and blood may often pulse, or spurt out of the wound. Severe bleeding, or hemorrhage, can result in shock or death if not treated promptly. Stopping the loss of blood in these cases is essential. If a victim loses too much blood, even CPR will not keep the person alive, because there will not be enough blood to deliver oxygen from the lungs to the body.

TYPES OF BLEEDING

There are three types of bleeding:

- Arterial bleeding is the loss of blood from an artery. Characterized by bright red blood that spurts with each heartbeat, arterial blood loss is severe and hard to control. Give it first priority for treatment.
- Venous bleeding is blood loss from a vein. Venous bleeding is characterized by a steady flow of dark blood.
- Capillary bleeding is the loss of blood from the smallest blood vessels, the capillaries, and is usually characterized by a slow flow of blood.

First aid treatment in all of these cases includes stopping the flow of blood and preventing infection.

DIRECT PRESSURE

In most cases, applying continuous, direct pressure to a wound is the best way to control bleeding. To apply direct pressure, place a dressing over the wound. A dressing should be:

- Sterile; If a sterile dressing is not available, use a clean cloth (a washcloth, towel, or handkerchief).
- Larger than the wound.
- Thick, soft, and compressible so pressure is evenly distributed over the wound.
- Lint free.

If a clean cloth or gauze is not available, use clothing or your bare hands or fingers — whatever is the cleanest. Continue applying pressure and bleeding should begin to slow or stop within thirty minutes.
STOPPING INFECTION

Even the slightest wound requires immediate cleansing. The best way to clean wounds is to wash them with soap and water. At home, use water from the faucet. On a hike, use water from a canteen or the clear running water of a stream. If available, use an antiseptic cleanser instead of soap. Wait until the skin around the wound dries, then put on a bandage. If available, apply an antiseptic cream to the wound before bandaging it.

For a minor wound, cleaning and bandaging it is probably all that is required. Deep wounds, wounds made by animal or human bites, and wounds contaminated by dirt, rust, or other items require medical treatment. Clean and bandage these wounds, and get medical assistance as soon as possible. If a wound contains glass or other objects stuck into the flesh, do not remove them unless they wash out of the wound easily.

CONTROLLING BLEEDING TO EXTREMITIES

In most cases, direct pressure is the best way to stop bleeding of wounds to the extremities. As you apply direct pressure, keep the injured limb elevated above the heart to slow the flow of blood out of the body.

After initially applying direct pressure, you may want to apply a pressure bandage by applying a bandage snugly, using overlapping turns with a roll of gauze. Do not tie the pressure bandage so tightly that it restricts blood flow to the lower part of the limb. If fingertips or toes appear bluish, or if there is no pulse below the dressing, loosen the material used to secure the dressing immediately. Once you apply a pressure bandage, only qualified medical personnel should remove it.

PRESSURE POINTS

In case of severe bleeding that does not slow or stop using direct pressure, finger pressure may be applied to the pressure point on the injured limb between the wound and the heart. Pressure points are locations on the body where arteries are close to the surface. By applying pressure at these points, you slow or stop the flow of blood through the artery.

The principal pressure points for the arms and legs are shown in the following illustration. As with mouth-to-mouth resuscitation and CPR, it is better to have first aid training on pressure points before actually using this technique to stop bleeding. If done incorrectly, you may damage healthy tissue fed by the artery you are constricting.
TOURNIQUET

If heavy blood loss continues, as from amputation, it may be necessary to use a tourniquet. Caution: Since a tourniquet is a constricting band that stops the flow of blood below it, it can kill the limb to which it is applied. Therefore, only use a tourniquet if no other method works to stop the bleeding and you believe the injured person’s life is in danger. To apply a tourniquet:

1. Fold a cloth until it is approximately two inches wide and long enough to go around the injured limb.

2. Tie the material in a loop and position it two to four inches above the wound, but not over a joint.

3. Pass a rigid object, such as a stick, under the tourniquet loop and twist it until the bleeding stops.

4. Tie off the end of the stick with another piece of cloth or string to prevent it from unwinding.

5. Mark the victim’s forehead with a “T” to alert medical personnel that you have applied a tourniquet.

If it is necessary to cover the victim with a blanket, do not cover the tourniquet to make it easier for medical personnel to spot. Once you apply a tourniquet, do not loosen or remove it. As with a pressure dressing, only qualified medical personnel should remove a tourniquet. Remember, use a tourniquet only as a last resort when all other attempts to stop the bleeding fail.

CONTROLLING BLEEDING TO THE HEAD AND TORSO

SCALP INJURIES

For wounds to the scalp, use a pressure dressing. If brain tissue is exposed, tie the dressing loosely over the wound. Do not press the brain tissue back into the open wound.
FACIAL INJURIES

Control bleeding from facial wounds by using a pressure bandage. Position the victim to prevent him or her from breathing blood. Victims who have sustained a severe blow to the head should be kept under close observation as they may have brain damage and could require rescue breathing.

CHEST INJURIES

A chest injury may result in an open chest wound, which could lead to air leaking from a lung and the collapse of a lung. If conscious, have the victim breathe out and apply some material such as plastic wrap or foil to the wound. Bind a pressure bandage tightly to the wound to prevent leakage of air and slow down blood loss. Have the victim sit up, if possible, or lay that person on the injured side.

ABDOMINAL INJURIES

When an open abdominal wound has exposed visceral (internal) organs, cover the abdomen loosely with dressings. Do not force the organs back into the body cavity and do not give victims with abdominal wounds any food or water.

CONCLUSION

Severe bleeding from wounds in which arteries or veins are cut can be life-threatening to an injured person. Therefore, controlling the loss of blood is second in importance only to restoring breathing and circulation. In most cases, applying direct pressure to a wound is the best way to control bleeding. Cleansing a wound to stop infection is also extremely important. If you know these two facts, and the other details on controlling bleeding to the extremities, head, and torso, you can successfully accomplish the second life-saving step in an emergency situation.
